Outline

Outline

Introduction

- This work was supported by the National Science Center grant *Towards census-like statistics for foreign-born populations – quality, data integration and estimation* (NCN OPUS 22 2020/39/B/HS4/00941).

Introduction

- In this study I would like to present initial results regarding the use of big data from mobile phones for official statistics.
- I use data from 2018 to 2021 collected through programmatic advertising systems from over 40 million smartphones in Poland.
- I focus on foreigners, their characteristics and how long they stay in Poland (up to 3 months, 3-12 months, more than 12 months).
- The methodological part covers the correction of misclassification errors based on a validation study and multiple imputation.

Outline

Data sources on population in Poland

- A *foreigner* is defined as a person residing in Poland who is not a Polish citizen (Census 2021 definition).
- Information about Polish citizens and some foreigners, including their ID called **PESEL** is maintained in the population register. PESEL is required to apply for work, insurance, or health services. It will be mandatory from 2023.
- Most foreigners have a PESEL ID but may use other IDs, such as visas or passports.
- According to Census 2021 (ultimo 31.03.2021), over 1.6 million foreigners lived in Poland, including close to 1.2 million Ukrainians.
- Now, because of the Russian aggression against Ukraine about 1 million more Ukrainians reside in Poland (90% of them are women and children).

Data sources on population in Poland

- Population register (**PESEL**),
- Social Insurance Institution register (**ZUS**; insured and employed; length of employment or insurance),
- National Health Service register (**NFZ**),
- Office for Foreigners register (**UDSC**; documents; documents validity period),
- Ministry of Foreign Affairs (**MSZ**; visas, visa validity periods) – currently only report aggregated data to Statistics Poland
- Border Guards register (**SG**; border crossings, undocumented migrants; enter and exit dates) – currently only report aggregated data to Statistics Poland.

Big data sources on population in Poland

- Most studies on the use of big data sources to measure the population rely on mobile phone data (CDR, signaling) or social media (e.g. Facebook).
- In this study I use different big data, which come from *programmatic* advertising systems.
- Programmatic advertising is a way to automatically buy and optimize digital campaigns on smartphones.
- Before a user sees an ad on their device there is a micro auction on whether to present a given ad.

Programmatic advertisement system

- Transactions are based on information about the device: system, location, apps, and activities.
- Each smartphone has a unique ID – **GAID** (Android) or **IDFA** (iPhone). ID changes with the smartphone or when the user resets it (it is possible on Android or iOS $<$ 13).
- I obtained data from the **Selectivv** company that collects data from over 40 million smartphones (from multiple mobile providers). After deduplication, the dataset contains nearly 33 million users. Selectivv also uses external databases to enhance collected information.
- Selectivv applies a rule-based and machine-learning algorithm to obtain socio-demographic variables.

Advertising IDs – an example

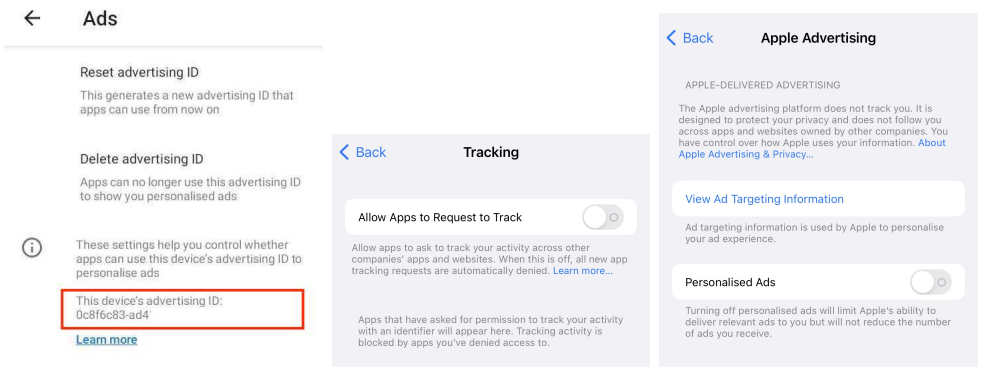

Figure 1: Google Ads ID (left) and Apple Identifier for Advertisers (center and right)

CDR vs programmatic systems

Table 1: Comparison between CDR and programmatic systems

Characteristic	CDR	Programmatic
Unit	SIM card	Phone ID
Unit error	SIM card replacement	Smartphone replacement, ID reset or limiting access
Coverage	Single operator	Multiple operators
Collected data	Calls, SMS, BTS	Activity, System info, GPS
Background info.	Very limited	Limited but derived by ML
Observation	Only during calls / SMS	During activities on smartphone

Selectivv – quality and measurement

- users may use multiple smartphones (private, business)
  - $\sim$ 51 million SIM cards (Poland's population in 2021 was around 39 million),
  - $\sim$ 97% mobile phones coverage, $\sim$ 75% smartphones coverage in Poland,
  - $\sim$ 1% have two or more private smartphones,
  - $\sim$ 5% have one or more business smartphones,
  - on average one smartphone is used for about 2 years.
- Selectivv deduplicates GAID/IDFA based on geolocation (co-occurrence in night and day) and connections to Wi-Fi networks.
- Problems: *change of device* (in Poland around 2 years), *reseting GAID/IDFA* or *limiting tracking*.

Selectivv – quality and measurement

Selecivv does not know the identity of individual smartphone users. They use rule-based and machine learning algorithms to derive background information.

- Country of origin (a proxy for citizenship) – based on system language, length of stay in Poland and traveling abroad, and changing SIM card to a local operator.
- Sex and age – based on activity: apps, websites or location.
- Length of stay – based on geolocation (e.g. weather apps). We obtained three groups *from 30 days to 3 months*, *3 to 12 months* and *over 12 months*.

Outline

Problems with big data

- over-coverage error – duplicates in the data,
- under-coverage error – non-smartphone users,
- measurement error – misclassification error due to different definitions or algorithms (Schenkel and Zhang 2022, Pankowska et al 2018, Pavlopoulos and Vermunt 2015, Grow et al. 2022),
- non-probability samples – estimation based on a non-representative sample.

Validation study

- To assess classification error a validation study was conducted (cf. two-phase studies).
- A stratified sample was drawn, where strata were defined by country of origin provided by Selecivv: Poland, Ukraine, Belarus.
- The survey was conducted via advertising systems on smartphones.
- The initial sample size was about 55k, while the final sample contains 501 respondents.
- The questionnaire included questions about country of origin, sex, age, length of stay, and usage of smartphones.

Methods to deal with misclassification

We can classify methods based on where the measurement error is observed:

- target variable (Y^*; cf. Adhya et al. 2022),
- auxiliary variables (X^*),
- both Y^* and X^*.

Then, the selection of the appropriate method depends on whether results from a validation study are available, i.e. whether we have access to individual-level data or only estimates or errors.

Possible methods to deal with misclassification in all variables

- SIMEX and MCSIMEX approach – correction of regression parameters based on a misclassification matrix for each variable (Carroll et al. 1996; Lederer and Küchenhoff 2006, Küchenhoff et al. 2006a,b).
- Multiple imputation where true X, Y are imputed based on validation sample (X, X^*, Y, Y^*) where Y^*, X^* are variables suffering from measurement error (Rubin 1996, van Buuren and Groothuis-Oudshoorn 2011).

Comparison with admin data – age

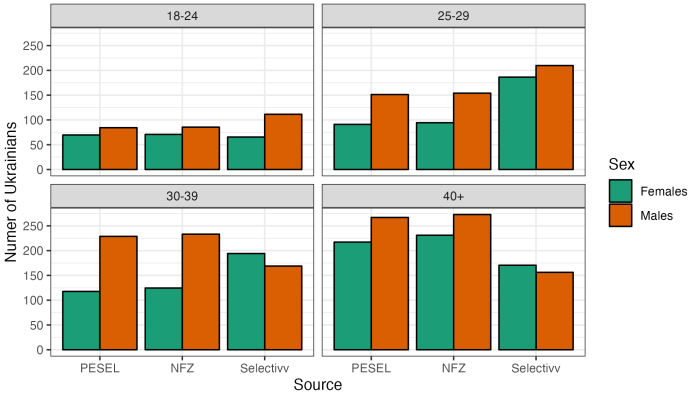

Figure 3: Comparison of sex and age between two registers and big data

Comparison with admin data over time

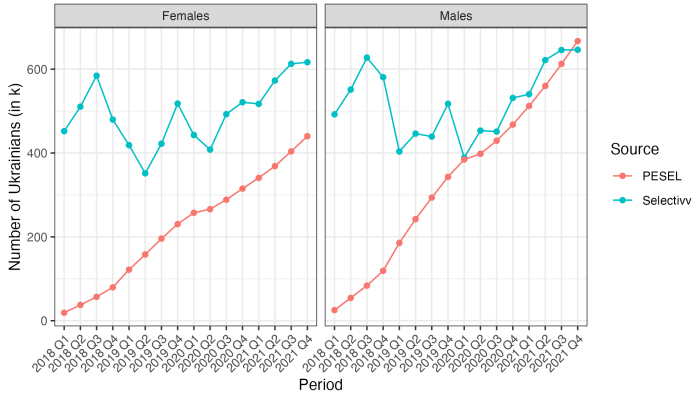

Figure 4: Comparison of sex between PESEL and big data

Validation study – results

Table 4: Accuracy of Selectivv data for socio-demographic variables

Variable	Level	Accuracy	Sample size
Country	Belarus	96.0	101
	Poland	96.8	247
	Ukraine	93.5	153
Sex	Females	87.3	221
	Males	89.3	280
Age	18-24	88.1	236
	25-29	84.8	151
	30-39	92.2	64
	40+	96.0	50
Length of stay	3m	61.4	44
	3m-12m	78.6	112
	12m+	97.9	97

Validation study – length of stay

Table 5: The length of stay based on Selectivv data (rows), and declarations from the validation sample (columns)

	3m	3m-12m	12m+
3m	27 (61.4)	16 (36.4)	1 (2.3)
3m-12m	0 (0.0)	88 (78.6)	24 (21.4)
12m+	1 (1.0)	1 (1.0)	95 (98.0)

Validation sample – correlations

Table 6: Correlation between the length of stay and demographic variables from the validation study and the ZUS register

Variable	χ^2	df	p-value	Cramer's V
with Selecivv data				
Country	0.32	2	0.85	0.04
Age	4.13	6	0.66	0.09
Sex	10.17	2	0.01	0.21
with declarations				
Country	1.00	2	0.61	0.06
Age	3.78	6	0.71	0.09
Sex	4.95	2	0.08	0.14
ZUS data (2021Q4)				
Country	958.89	2	< 0.001	0.04
Age	19376	6	< 0.001	0.12
Sex	3338.7	2	< 0.001	0.07

Length of stay – admin data

- Currently, Statistics Poland does not publish any statistics about the length of foreigners' stay in Poland.
- There are several possible sources but the only one available at unit level is the *Social Insurance Institution* register (ZUS).
- Employment / Insurance registers were previously used by (reference) for capture-recapture studies.
- In this study we obtained the length of stay for 2021 based on insurance and employment periods.
- This variable uses information about the dates of employment and insurance and is calculated with reference to the end of a given quarter.
- Note that the ZUS register contains only around 700k out of 1.2 million ($\sim 60\%$) Ukrainians included the PESEL/NFZ register.

Length of stay – comparison

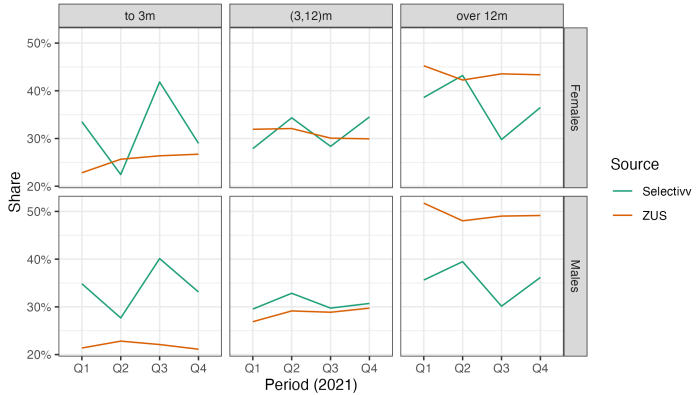

Figure 5: Comparison of the length of stay between ZUS and big data

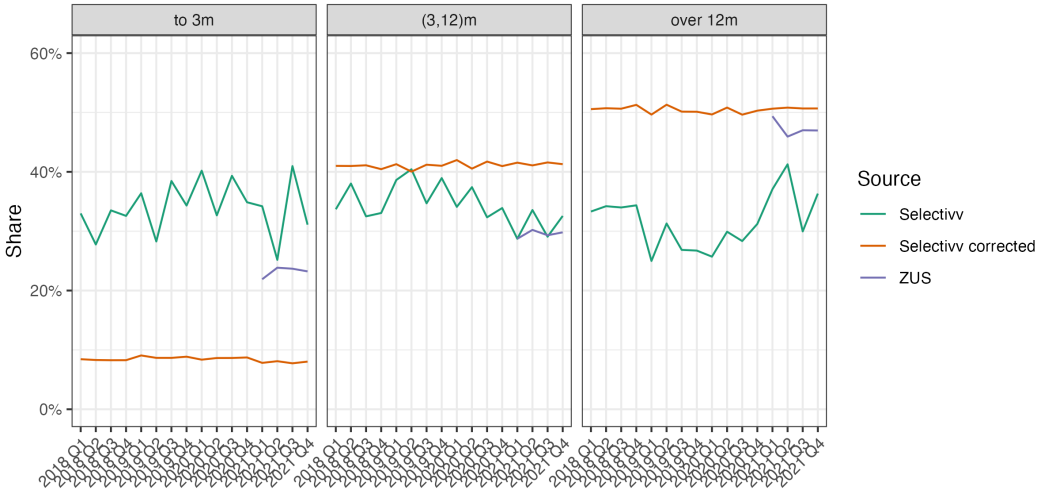
Length of stay – point estimates



Outline

Summary

- The study investigated the use of big data for official statistics.
- In particular, I focused on the length of foreigners' stay in Poland as measured on the basis of smartphone data.
- While the large amount of data makes it interesting, the errors corrected with coverage and measurement are substantial.
- Misclassification is observed in all variables and the error varies across the variables.
- The only reference data on the length of stay come from insurance and employment of about 700k of foreigners residing in Poland.
- Unfortunately, analysis was limited by the accessibility to data from the PESEL Population register, visas, and border crossings.
